# What are complex numbers?

# What are complex numbers?

## Motivation: working with “impossible” numbers

At first, this expression looks like complete nonsense:

$$\sqrt{1 + \sqrt{-3}} + \sqrt{1 - \sqrt{-3}}$$

But is it really?

## Benefit: solving quadratic equations

Find  $x$  so that  $x^2 - 2x + 2 = 0$ .

- As  $D = -4 < 0$ , there are **no real solutions**
- If we set  $i = \sqrt{-1}$ , then we find **two solutions**.

OK to calculate with  $i$ , as long as we remember

$$i^2 = -1.$$

# Number systems

Symbol	Elements	Used for
$\mathbb{N}$	0, 1, 2, ...	Counting
$\mathbb{Z}$	..., -1, 0, 1, 2, ...	Adding/subtracting
$\mathbb{Q}$	Fractions $n/m$	Dividing
$\mathbb{R}$	$\mathbb{Q}$ and irrational numbers: $e$ , $\pi$ , ...	Limits
$\mathbb{C}$	$a + ib$ , with $a, b \in \mathbb{R}$	Solving equations

# Cartesian and polar representation

# Graphical representation of complex numbers

If  $z = x + iy$  is a complex number, then

- $\operatorname{Re}(z) = x$  (the real part)
- $\operatorname{Im}(z) = y$  (the imaginary part)

are both real numbers and  $(x, y)$  determines a point in the plane.

Argand plane:

- $x$ -axis: Real axis
- $y$ -axis: Imaginary axis

## Example

In the complex plane, find the location of:

- $z_1 = 1$
- $z_2 = 2 + 3i$
- $z_3 = -2i$
- $S = \{z \in \mathbb{C} : \operatorname{Re}(z) \leq 1\}$

# Modulus and argument

- **Modulus** (absolute value) of  $z$ : distance to the origin.

$$|z| = d(z, O) = \sqrt{x^2 + y^2}.$$

- **Argument** of  $z$ : angle with positive  $x$ -axis.

$$\text{Arg}(z) = \theta \in (-\pi, \pi] \text{ if}$$

$$\tan \theta = \frac{y}{x}.$$

## Finding the argument (continued)

If  $z$  is in quadrant 1 or 4, then

$$\theta = \tan^{-1}\left(\frac{y}{x}\right).$$

Otherwise ( $z$  in quadrant 2 or 3)

$$\theta = \pi + \tan^{-1}\left(\frac{y}{x}\right).$$

## Polar representation of complex numbers

If  $r$  is the modulus and  $\theta$  the argument of  $z = x + iy$ , then

$$\begin{cases} x = r \cos \theta \\ y = r \sin \theta \end{cases}$$

This gives us the **polar representation of  $z$** :

$$\begin{aligned} z &= x + iy \\ &= \boxed{r(\cos \theta + i \sin \theta)} \end{aligned}$$

## Example

Find the polar representation of

- $z_1 = i$
- $z_2 = 1 + i$
- $z_3 = -\sqrt{3} - i$

## Complex conjugate

If  $z = x + iy$ , then the **complex conjugate**  $\bar{z}$  is given by

$$\bar{z} = x - iy.$$

Properties:

- ①  $\operatorname{Re}(\bar{z}) = \operatorname{Re}(z)$
- ②  $\operatorname{Im}(\bar{z}) = -\operatorname{Im}(z)$
- ③  $|\bar{z}| = |z|$
- ④  $\operatorname{Arg}(\bar{z}) = -\operatorname{Arg}(z)$

# Calculating with complex numbers

# Adding and subtracting complex numbers

Complex numbers can be added/subtracted component-wise: if  $z = x + iy$  and  $w = a + ib$ , then

$$\begin{aligned}z \pm w &= (x + iy) \pm (a + ib) \\ &= (x \pm a) + i(y \pm b)\end{aligned}$$

This has a nice geometric interpretation via the **parallelogram rule**:

- Draw a parallelogram with sides  $z$  and  $w$
- $z + w$  is at the end of the diagonal

# Multiplying complex numbers

If  $z = x + iy$  and  $w = a + ib$ , then (using  $i^2 = -1$ )

$$\begin{aligned}zw &= (x + iy) \cdot (a + ib) \\ &= (xa - yb) + i(ya + xb)\end{aligned}$$

Properties:

- ①  $z\bar{z} = |z|^2$
- ②  $\overline{zw} = \bar{z} \cdot \bar{w}$

# Product of complex numbers in polar form

Write

$$w = r(\cos \theta + i \sin \theta)$$

$$z = s(\cos \phi + i \sin \phi)$$

Then we get the following nice form for the complex product:

$$wz = \underbrace{rs}_{|wz|} (\cos(\underbrace{\theta + \phi}_{\text{Arg}(wz)}) + i \sin(\theta + \phi))$$

In particular, we get

- $|wz| = rs = |w||z|$
- $\text{Arg}(wz) = \theta + \phi = \text{Arg}(w) + \text{Arg}(z)$

## De Moivre's theorem

From the product rule, we get

$$|z_1 z_2 \cdots z_n| = |z_1| |z_2| \cdots |z_n|$$
$$\text{Arg}(z_1 z_2 \cdots z_n) = \text{Arg}(z_1) + \cdots + \text{Arg}(z_n).$$

Substituting  $z_1 = \dots = z_n = \cos \theta + i \sin \theta$  gives us **De Moivre's theorem**:

$$(\cos \theta + i \sin \theta)^n = \cos(n\theta) + i \sin(n\theta).$$

# Division of complex numbers

We put

$$\frac{z}{w} = \frac{x + iy}{a + ib}.$$

- How can we make sense of this complex number?
- Multiply by the conjugate:

$$\frac{z}{w} = \frac{x + iy}{a + ib} \frac{a - ib}{a - ib} = \frac{ax + by}{a^2 + b^2} + i \frac{ay - bx}{a^2 + b^2}.$$

Properties:

$$|z/w| = |z|/|w| \quad \text{and} \quad \text{Arg}(z/w) = \text{Arg}(z) - \text{Arg}(w).$$

## Useful properties of complex numbers

- $\overline{z + w} = \bar{z} + \bar{w}$
- $\overline{zw} = \bar{z}\bar{w}$
- $\overline{\bar{z}} = z$
- $zw = 0$  iff  $z = 0$  or  $w = 0$

Property: to take the conjugate of a complicated expression, it suffices to take the conjugate of every term.

Example: Given  $z = i\frac{Z-1}{Z+1}$ , compute  $\bar{z}$ .

## Examples

- Find the modulus and argument of  $z = (3 + 5i)(4 - 2i)$ .
- Simplify the complex number  $z = \frac{7+3i}{4i}$ .

## Examples

Simplify the following complex numbers as much as possible:

- $z = \frac{1+i}{1-i}$
- $z = i^{2022}$

## Caveat

Keep in mind that, for complex numbers,

$$\sqrt{ab} \neq \sqrt{a}\sqrt{b}.$$
